Liam Sharkey

1. Programming Languages (5 points)

This project is entirely gdscript at the moment. It's the language provided by godot and is effective and easy to use. There's a possibility that a niche requirement will have us using something like c in the future, but for now it's gdscript

2. Platforms, APIs, Databases, and other technologies used (5 points)

This project is based on the godot platform and engine. The closes thing to a database that is used so far is the asset store for placeholder textures and sprites.

3. Execution-based Functional Testing (10 points)

Functional testing has been done in playtests and limited observing if systems work how we expect them to. Each feature is testing one at a time as it is implemented, rather than one thorough test sequence. Things such as does the camera follow the player, does the player walk through walls, are questions asked when you walk into the tall grass, are all tested as a step in implementation. During these playtests we also go back to check if a new feature has broken old ones.

4. Execution-based Non-Functional Testing (10 points)

Nonfunctional testing is also done during implementation to a lesser scale. These would only cover the quality of a feature, such as camera jitter, framerate loss, and texture clipping are common quality issues we would look for

5. Non-Execution-based Testing (10 points)

No non execution-based testing has been done at this stage in the project. If we ever get to code or structure reviews it will likely be the last step of the process.
